Telescope Array Configuration

- Located 200 km SW of Salt Lake City
- 507 surface units on 1.2 km rectangular grid
- Total area: 680 km²
- SD augmented by 3 air fluorescence stations
- SD commissioned in May 2008

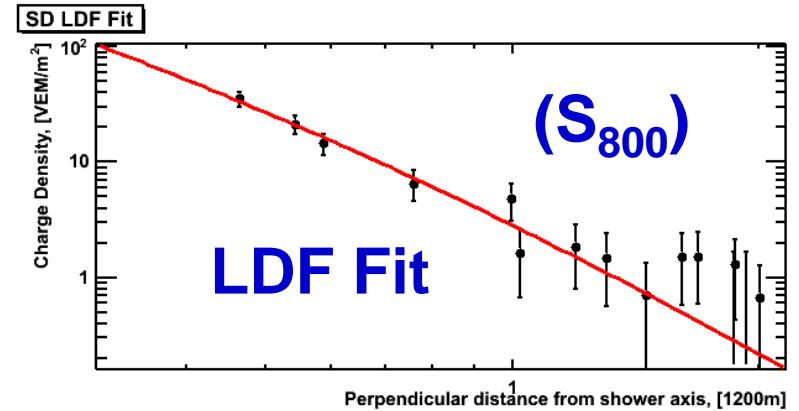

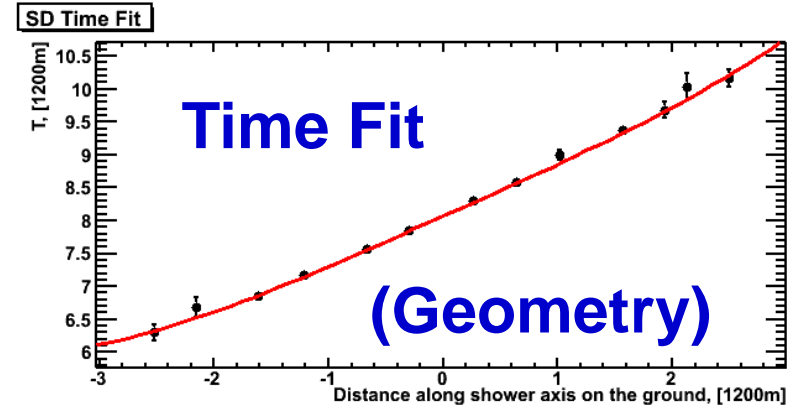

TA Surface Detector

- Powered by solar cells; radio readout.
- Self-calibration using single muons.
- In operation since May, 2008.

Typical Event: Surface Detector

Each counter self-calibrates every 10 min

TA Fluorescence Detectors

Refurbished
from HiRes

Observation
started Dec.
2007

Middle Drum

14 cameras/station
256 PMTs/camera

~30km

256 PMTs/camera
HAMAMATSU R9508
FOV~15x18deg
12 cameras/station

New FDs

Observation
started Nov.
2007

6.8 m²

Long Ridge

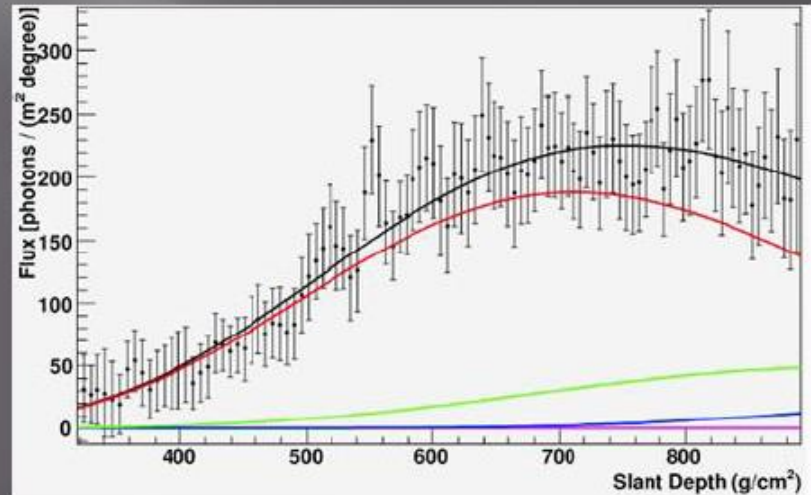

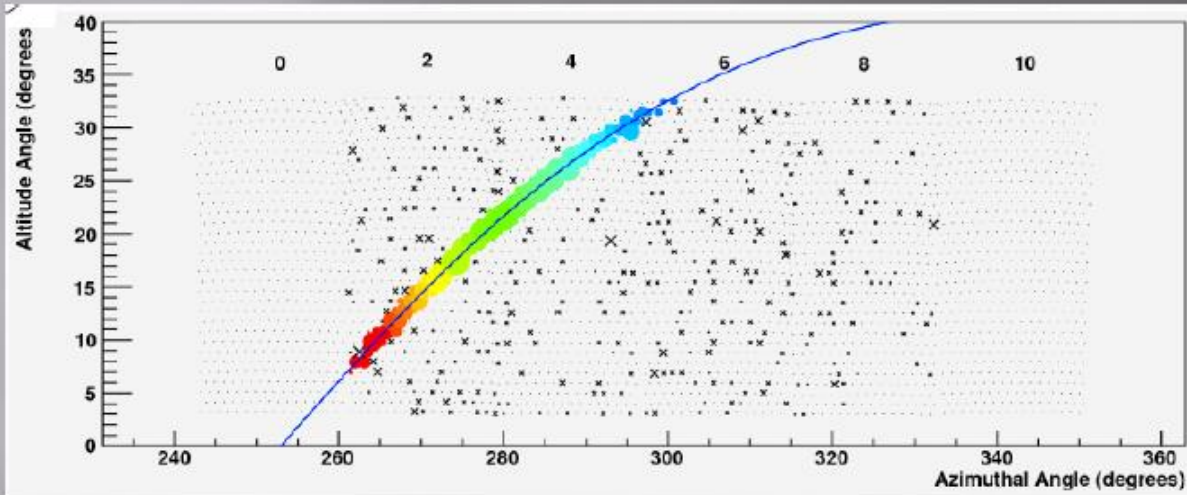

Black Rock Mesa

Observation
started Jun.
2007

~1 m²

Typical Event: Fluorescence Detector

A Careful Analysis Method

- **No CIC approach, but rather full Monte Carlo**
 - Simulate the data the same way it is observed by writing out the MC events in same format as data.
 - Fits tuned to data using functional form observed by previous experiment (i.e. AGASA) to ensure model independence.
 - Analyze the MC with the same programs used for data.
 - Confirm with data/MC comparison plots.

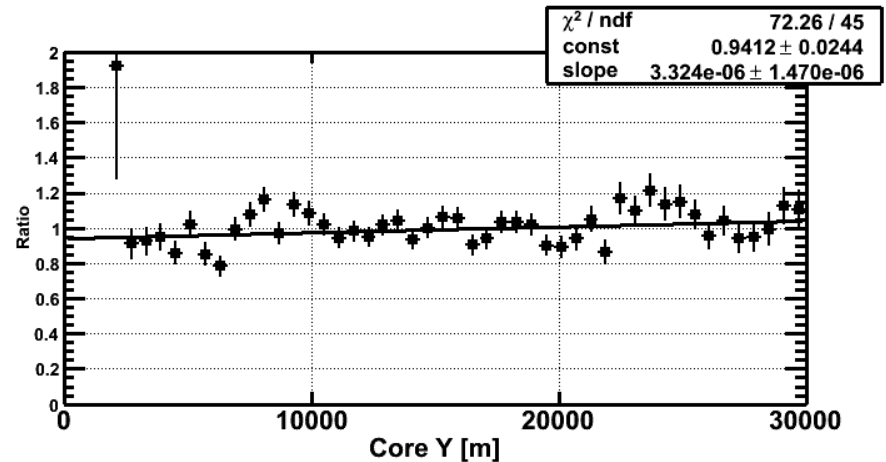

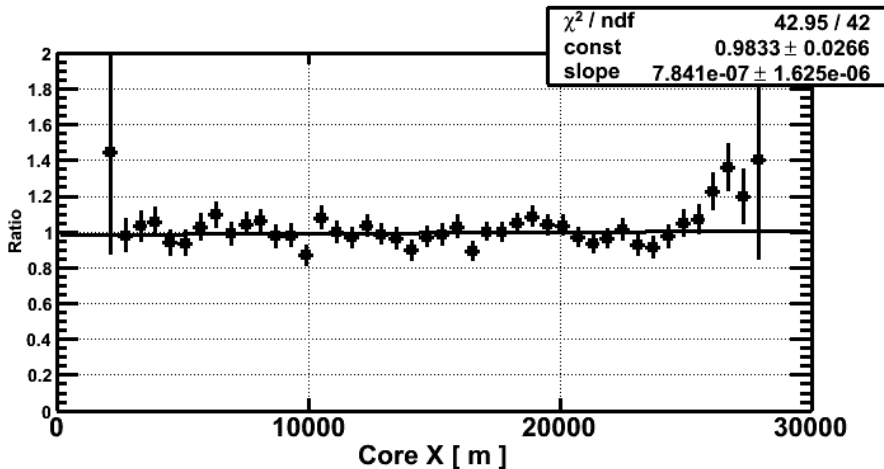

SD Analysis: Geometric Data/MC Comparisons

Zenith angle

Azimuth angle

SD Analysis: Geometric Data/MC Comparisons

Core Position (E-W)

Core Position (N-S)

SD Analysis: Energy Scale

- SD and FD energy estimation disagree
- FD estimate possesses less model-dependence
- Set SD energy scale to FD energy scale using well-reconstructed events from all 3 FD detectors
- **27% renormalization w/QGSJET-II-03 protons**

Anisotropy Studies

- Correlation with AGNs (as per Auger)
- Autocorrelation (as per AGASA)
- Correlation with Large Scale Structure
- “Hotspot” Search

Anisotropy Data Set

- 8 May 2008—13 May 2013 (5 years)
- $<55^\circ$ zenith angle
- **2130** events above **10 EeV**
- **132** events above **40 EeV**
- **52** events above **57 EeV**

Cosmic Ray Origins

Search for AGN Correlations

- Parameters from the Auger 2007 publication:
 - Veron-Cetty & Veron catalog 2006
 - Redshift $0 < z < 0.018$ 465 AGN
 - Angular separation $< 3.1^\circ$
- **17/42** events **$p=0.017$**

Autocorrelation

- No evidence of small scale clustering (as per AGASA)
- Departure from isotropy of 3σ at $\sim 20^\circ$

Correlation with LSS

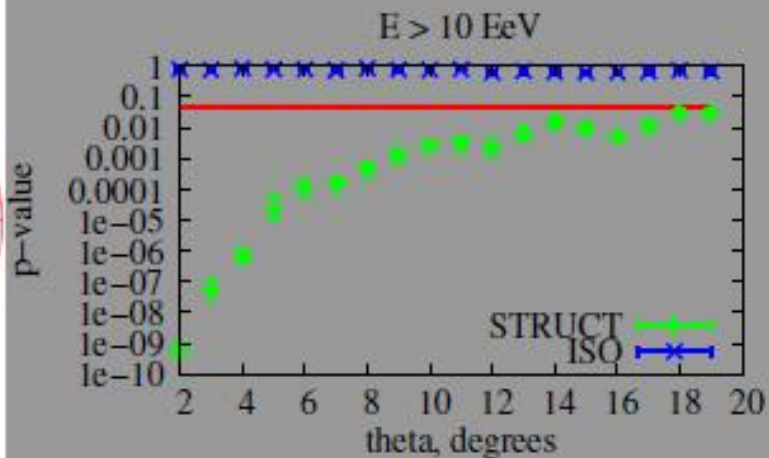

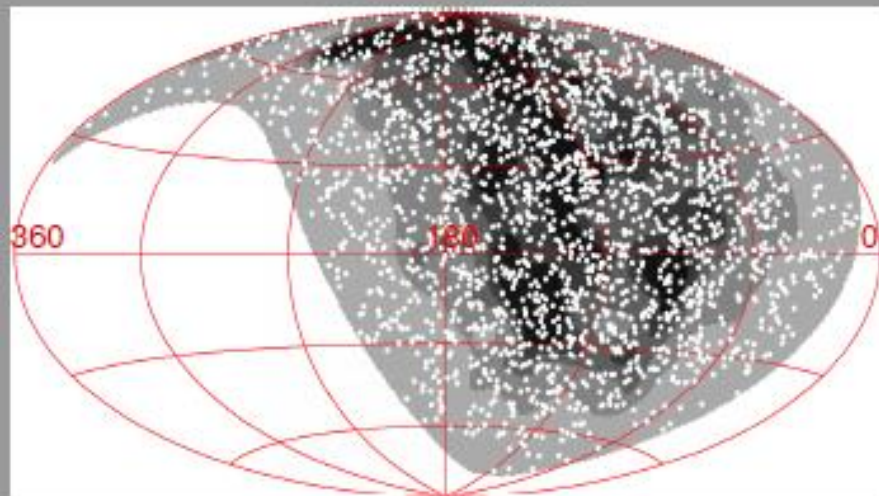

Motivation:

- TA composition consistent with protons
- Protons @ 10^{20} eV only expected to have $2-5^\circ$ deflection at GZK distances
- Hence arrival directions at the highest energies should correlate with LSS
- Only free parameter: deflection angle

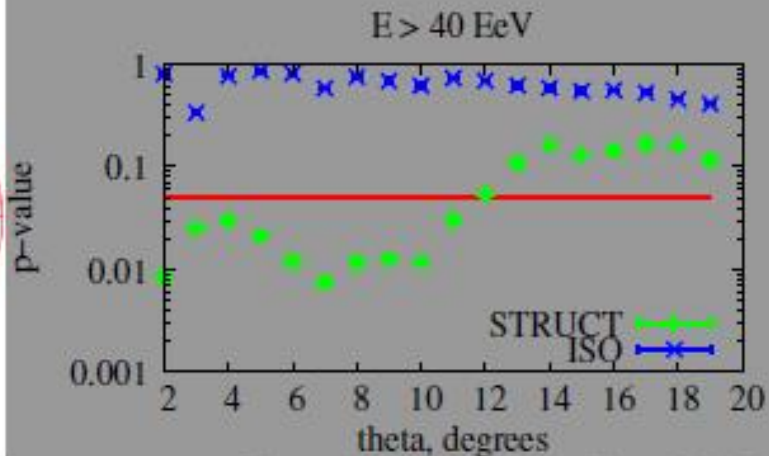

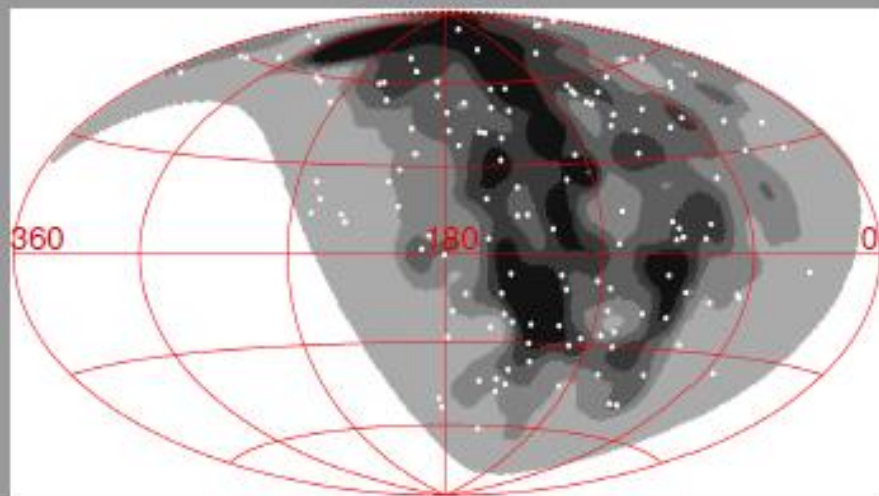

Correlation with LSS

$E > 10$ EeV

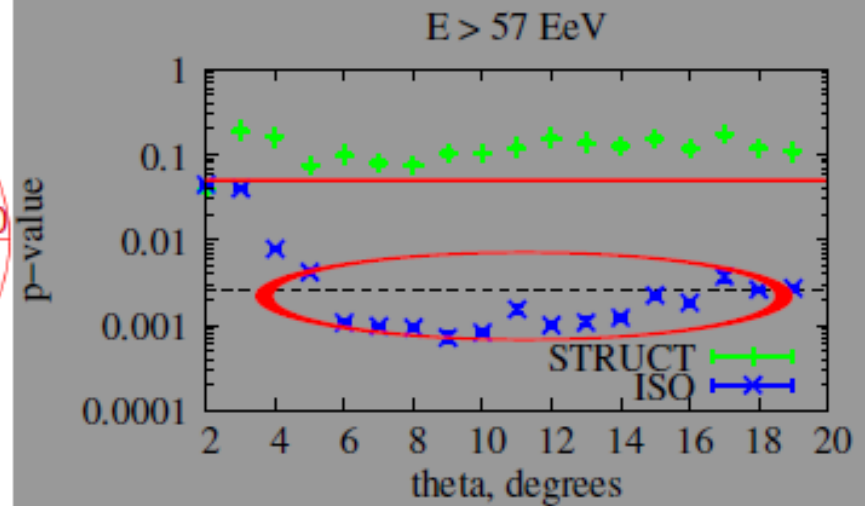

$E > 40$ EeV

Correlation with LSS

$E > 57 \text{ EeV}$

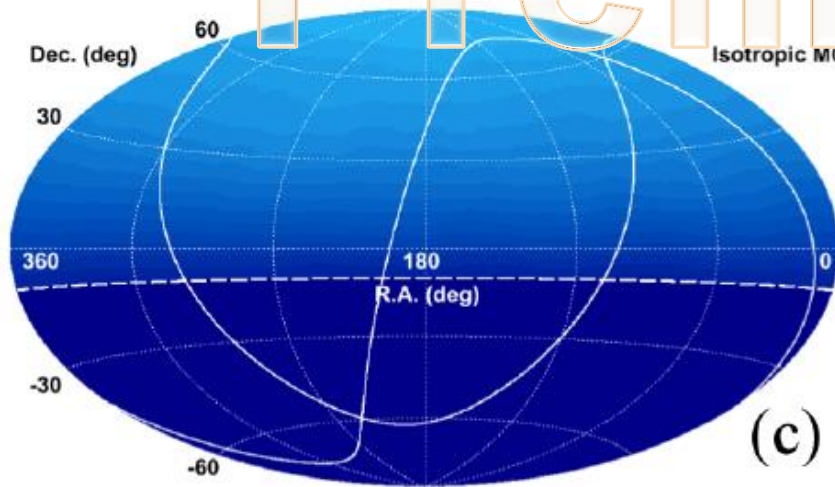

- ▶ High energy $E > 57 \text{ EeV}$ data are not compatible with isotropy at $\sim 3\sigma$ (pre-trial)

Needed: More Statistics

- Telescope Array event set optimized for energy spectrum studies
- Looser cuts are acceptable for anisotropy studies
- **52** events >57 EeV \rightarrow **72** events >57 EeV

The TA Hotspot

Preliminary

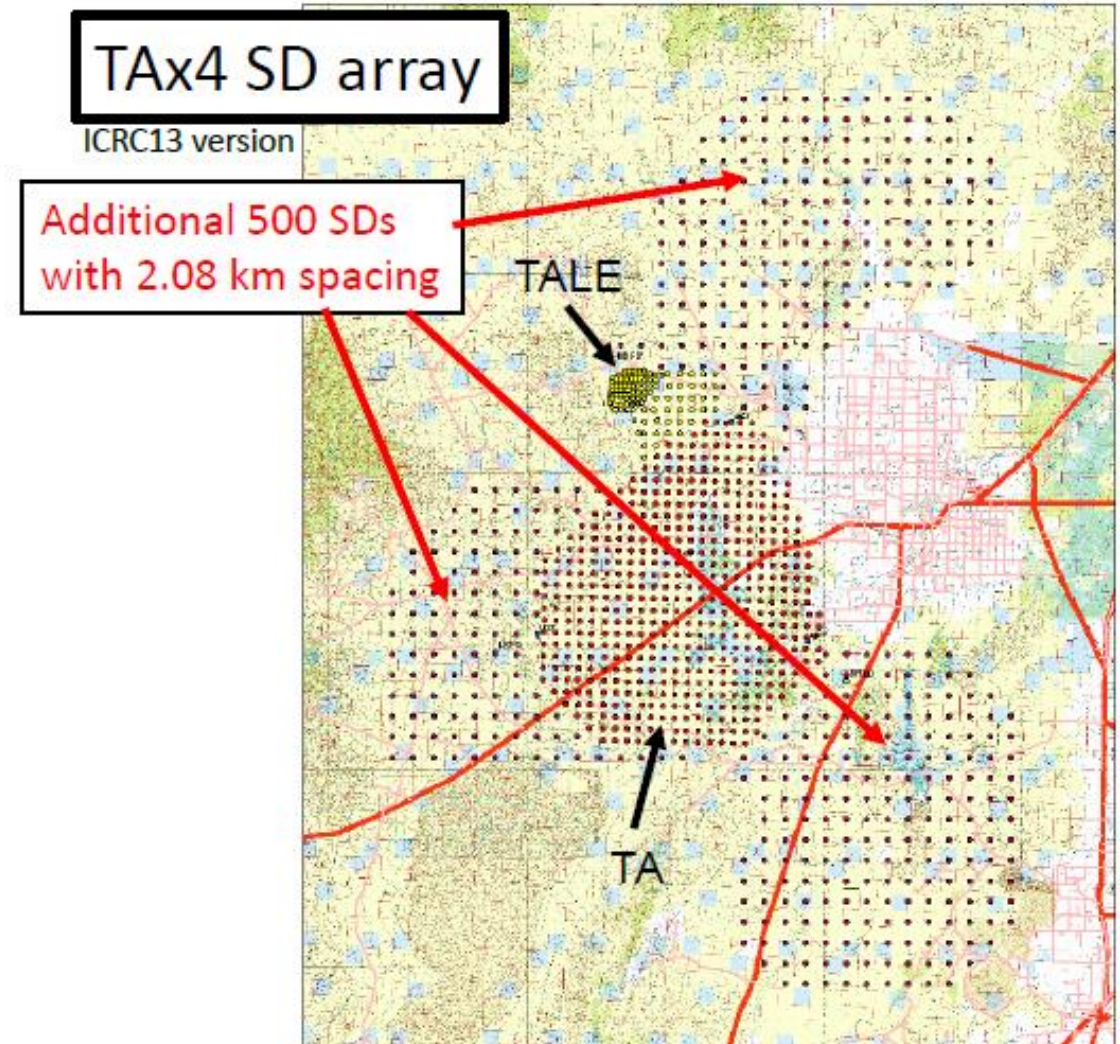

Hotspot Description

- 20° oversampling
 - No scanning
- Maximum: 19 events/4.5 expected 5.1 σ
- Chance of a 5.1 σ maximum **anywhere** in a isotropic set: 3.6 σ

If we're going to study this hotspot, we need a lot more data...

- TAx4
 - **500** additional SD's with **2.08 km** spacing
 - One additional FD composed of recycled HiRes-II components

Conclusions

- TA possesses the largest aperture for UHECRs in the Northern Hemisphere.
- Several different analyses point to anisotropy above at energies above 57 EeV
- More data needed
